Translation from: Referativnyy zhurnal, Geologiya, 1957, Nr 3,
p 136 (USSR)

AUTHOR: Smirnov, A. V.

TITLE: Sapropel Reserves of Nero Lake; an Experiment on Using
Sapropel as Soil Conditioner, and Methods of Productive
Extraction (Zapasy sapropeley ozera Nero, opyt ikh
ispol'zovaniya na udobreniye i sposoby proizvodstvennoy
dobychi)

PERIODICAL: Tr. Labor. sapropel. otlozheniy. In-t lesa AN SSSR,
1956, Nr 6, pp 201-213

ABSTRACT: The store of sapropel in Lake Nero amounts at least to
250 million m³. Agricultural field experiments and
chemical analyses show it to have a high value as a
soil conditioner in agriculture. The content of humus
(from 3 to 17 percent) and of calcium (from 10 to 32
percent) makes it especially valuable for conditioning
podsol and gley soils.

Practical instructions for nitriding steel. O. I. VER AND A. V. SMIRNOV. *Sovetskheniya Vsesoyuznogo Inst. Metal.* 1931, Nos. 1-2, 17-22. Instructions for nitriding steel with NH_3 are given and also details of the furnace and microphotographs of samples. The temp. should be around $490-510^\circ$, pressure of NH_3 not over 10 mm. in an air tight furnace and rate of flow of gas such that 30% of the NH_3 dissociates. The period of nitration is about 50 hrs. Heat treatment, annealing and polishing of surface of objects should all precede nitration. Cooling after nitration should take place slowly in the furnace itself in a stream of NH_3 . The NH_3 should be dried over unslaked lime or solid NaOH . Spots on the surface not to be nitrated should be tinned with a 50-50 Pb-Sn coat.

The nature of flakes (white spots of minute cracks) in connection with an investigation of turbine disks. A. L. BABOSHIN, A. V. SMIRNOV, A. P. TULYAKOV AND A. I. NORMARK. *Sootsicheniya Vsesoyuznogo Inst. Metal.* 1931, Nos. 3-4, 27-30.—Flakes, or white spots of minute cracks, found inside and on the surface of Ni-Cr, Ni and Cr steel products are the principal defects responsible for the rejection of 50% or more of turbine disks. An attempt was made to interpret the nature of these flakes and to find means for their combat. The study was made along the lines of chem. analysis, macrostructure of fracture, microstructure of the steel, mech. properties, critical points and effect of individual chem. elements on dendritic segregations. It is concluded that the flakes are closely related to the dendritic inclusions. Strains form along dendritic axes and in the interaxial spaces during the critical temp. interval of cooling and later cause the minute cracks or flakes. This difficulty can be overcome by a proper control of the cooling soon after casting or during and after forging. S. L. MADORSKY

<p>11X</p> <p>Preparation of emulsions for reversal. K. S. Lyulikov and A. V. Sushkova. <i>Photo-Kino Chem. Ind.</i> 1934, No. 2, 22-30. — It is concluded that: (1) Ordinary photographic emulsions of high sensitivity are not suitable for reversal since they give too high a fog in the positive. (2) Dilm. of the emulsion before coating improves the reversal image. (3) Dilm. of the emulsion with gelatin soln. has the same effect as dilm. with H₂O. (4) An increase in the concn. of bromide and Ag in the mix increases the positive fog. (5) The second ripening of the emulsion, after washing, has no effect upon the reversal characteristic. (6) KI added to the finished emulsion tends to increase the positive fog. (7) The mixing of emulsions of high and low sensitivity with corresponding difference in the grain size gives satisfactory results. Practical formulas for the manuf. of suitable emulsions of the NH₄ type are given. The sensitizers suggested are pinaeyanol, orthochrome T, pina-verdol and pinallavol. C. E. K. Deep nitriding. A. V. Smirnov and L. V. Beloruchev. *Repts. Central Inst. Metals* (Leningrad) No. 16, 127-33 (in German 133)(1934).—Three grades of steel were subjected to a nitriding process. Compos. of the steels was: (1) 0.84 C, 0.58 Mn, 1.45 Cr, 0.07 V, 0.06 Mo, 0.02 Al; (2) 0.39 C, 0.59 Mn, 1.40 Cr, 0.11 V, 0.24 Mo; (3) 0.74 C, 0.40 Mn, 1.76 Cr and 0.35 Al. The following nitriding method was used. After passing through a thermal treatment, the samples were placed in a nitriding elec. oven and heated first at 500° for 48 hrs. After this the temp. was varied cyclically every 5 hrs. between 540 and 600°, for a total period of 48 hrs. Finally the temp. was varied cyclically every 6 hrs. between the same temp. limits, for a total period of 100 hrs. At these temp. variations disocn. of NH_3 reached 8-10% at the lower temp. and 50-60% at the upper. The nitride coat thus obtained was on the av. 1.19, 1.48 and 1.15 mm. thick for the steels (1), (2) and (3). This shows that the sinusoidal method gives a deep nitrided coat, but at the same time it lowers the hardness of the treated samples.

Manufacture and properties of steel wire A. I. Baboshin, A. V. Smirnov and N. I. Maslov. *Izvestia Metalloproiz.* 15, No. 4, 23 (1942); *Chem. Zvesti* 1939, 1, 1690. Studies are reported on the influence of the degree of deformation and the heat treatment on the structure, the mech. properties and the resistance to corrosion of steel wire drawn from 18 to 1.4 mm. diam. and of the following composition: one specimen 0.37% C, 0.23% Si, 0.33% Mn, 0.36% P, 0.022% S, 0.02% Cu, 0.005% Nb, 0.005% P; another 0.65% C, 0.18% Si, 0.37% Mn, 0.011% P, 0.017% S and 0.013% Cu. The mech. properties (tensile strength, resistance to shock, bending strength, resistance to torsion, fatigue strength and the elastic limit) were investigated. On the basis of the expl. results it is recommended that in drawing the deformation should not exceed 75%, and that a final heat treatment at 250-300° increases the resistance to shock. The torsion strength cannot be concluded from the results of tests of bending strength; each test must be made independently. The torsion test detects defects due to too great deformation during drawing, while the bending test is a test of the plastic properties of the material.

PROCESSES AND PROPERTIES

Resistance of nitrided steels in gases. A. V. Smirnov and A. P. Khlopov. *Khim. Mashinostroyeniya* 8, No. 5, 26-8 (1939).—An investigation was made of the wear resistance of 2 nitrided steels under conditions approaching the service of rods of compressors and pumps which handle NH_3 , soda and other heavy chemicals. The following steels were tested: (1) C 0.34, Si 0.30, Mn 0.51, S 0.010, P 0.025, Cr 1.19, V 0.13, Mo 0.36, Ni 0.11%; and (2) C 0.30-0.38, Si 0.10, Mn 0.3-0.6, S 0.025, P 0.025, Cr 1.4-1.6, Al 0.8-1.2, Mo 0.40-0.60, Ni 0.5-0.7%. The nitriding was done in the usual manner for 8 hrs. at $590^\circ \pm 8$ hrs. at 550° . The nitrided specimens were then kept in an elec. oven at 200° for 10 hrs. and subjected to the action of air, H_2 , CO_2 , coke gas, and NH_3 (90% cracked), which were passed through the oven at the speed of 1 l./min. The specimens were then tested for wear resistance in an Amsler app. The results show that the 16-hr. nitriding process produced a 0.09-0.126 mm. layer which exceeded the wear of the rod by 4-6 times. Of the various gases only CO_2 and coke gas decreased the surface hardness of the nitrided layer, but the specimens did not show increased wear. The nitrided specimens which were treated with oxidizing gases gave in most cases less wear than for reducing gases. The nitrided steel (2) was 1.5 times more resistant to wear than steel (1). Both steels (1) and (2) are considered suitable for the manuf. of pump and compressor rods.

Search for methods of decreasing the burning of typographic alloys. A. V. Smirnov, R. A. Al'tan, and E. N. Golosova. *Poligraf. Proizvodstvo* 1951, No. 9, 25 8.—
In order to reduce the phys. loss of type alloys via gradual

oxidation and volatilization, while still retaining the desired characteristics, the following experimentally detd. methods can be applied. If the melting temp. is below 320–40° low vapor pressure bitumens and petroleum residues can be used as protective cover for the alloys. In the range 280–400° a mixt. of $ZnCl_2$ with 4% NH_4Cl is satisfactory, while at 300–400° $ZnCl_2$ mixts. with $MgCl_2$ or $CaCl_2$ are advantageous. Immersion of wood into the melts can be recommended only in combination with the salt covers listed above, or combined with a "floating lid" made of steel or cast iron which can be adjusted for different heights in the melt pot.
G. M. Kosolapoff

Smirnov, A.V.

Nitriding commercially pure iron to a high hardness.
A. V. Smirnov. Vestnik Mashinostroyeniya 32, No. 12, 43-6
(1963). Max. hardening of nitrided Fe is produced when
N-bearing martensite formed after quenching contains less
than 2.7% N. In conventional nitriding, N₂ content on
the surface is always higher than 2.7%; this leads to the soft
epsilon phase. The thickness of the epsilon phase could not
be reduced by nitriding at 700° in dil. NH₃. The martensitic
layer remained as before and the epsilon phase layer increased
with longer nitriding time. Holding the epsilon phase in H₂
+ N₂ for ten min. at 700° dissolved it completely, leading to
hardness of 755 and martensite surrounded by an easily
etchable dark phase resembling troostite, apparently a
ferrite-nitride mixt. produced by the decompn. of N-poor
austenite. The epsilon phase is easily decompd. by H₂ and
austenitic grains on the surface become impoverished in N
and lose their capability for undercooling, becoming trans-
formed on quenching into finely dispersed α and γ iron mixt.
having a hardness of 755 as compared with 317 for the
epsilon phase. A 20-min. hydration increases the develop-
ment of the α - γ phase and after 30 min. it penetrates into
the original martensitic zone, raising its hardness to 1070.
After 45 min. the epsilon phase is transformed to ferrite
having a hardness of 206. I. D. Gal

SHIRNOV, A.V.

Nitriding of technically pure iron to a high hardness. A. V. Shirnov. *Zhur. Tekh. Fiz.* 23, 1400-10(1953); cf. *ibid.* 24, 1022. Since the highest microhardness is shown after quenching by a nitrified martensite phase with a N content of less than 2.7%, a process has been worked out to obtain such a phase on the surface. The free energies and reaction consts. of various reactions involving α - and γ -Fe, nitrides, NH_3 , and dissolved and free N are tabulated. From these data it is shown that a solid soln. of N in α -Fe is formed at 705°, in γ -Fe at 289°. Fe_3N is formed at 320°, $\text{Fe}_2\text{N}(\epsilon)$ at any temp., and $\text{Fe}_4\text{N}(\epsilon)$ at 409°. The first, second, and last phases are metastable at room temp. in absence of NH_3 , the third and fourth are stable. A decrease of NH_3 pressure by diln. with a neutral gas suppresses the reactions leading to the formation of the ϵ -phase. Tests

were made with an NH_3 content varying from 10 to 100%. It is shown that at lower partial pressures of NH_3 (below 10%) or decreased dissocn. (below 85%), the diffusion of Fe and N leads to the formation of phases low in N at the surface. S. formed the ϵ -phase on the surface by nitriding at 700° in a mixt. contg. 17% NH_3 , then heated the product in a fully dissocd. mixt. for 10-75 min. and quenched in H_2O . A max. of microhardness was observed after a treatment of 30 min. If the temp. during nitriding is raised, the ϵ -phase disappears at 776°, an austenite phase at 825°, and the N content is depleted completely at 876° and 925°. Thus, high microhardness on the surface can be obtained at higher temps. than 700°. S. Pakswar

TITLE: Low Temperature Nitriding of Structural Steel. (Nizkotemperturnoye
azotirovaniye konstruktsionnoy stali).

PERIODICAL: Metallovedenie i obrabotka metallov, 1957, No. 2, pp. 49-54
(U.S.S.R.)

ABSTRACT: The experimental work was carried out by engineer R.V. Chudnovskaya
and four assistants. The authors investigated the possibility
of utilizing a nitriding process at a temperature below 400°C.
As a result to the experiments described a low temperature catalytic
process of nitriding at 380°C (60 to 80 hours) and 430°C (24 hours)
was developed which permits obtaining a Rockwell C hardness of 42 to
50 on structural alloy steel for a layer depth of 0.20 to 0.25 mm;
there is a steep decrease in the hardness from the surface towards
the core. By using the nitriding processes described here, the
development of Type II temper brittleness in nitrided components is
eliminated and the obtained nitrided layer is free of any brittleness
usually encountered on such layers in 38MnA steel. The process

TITLE: Low Temperature Nitriding of Structural Steel. (Nizkotemperturnoye azotirovaniye konstruksionnoy stali).

described here is used in a number of Soviet factories and two of the authors of this paper have an "author's certificate" for this process. Fig. 2 gives the change of the hardness and depth of the nitrided layer as a function of nitriding processes (380, 430 and 480°C with catalysts and 530 and 580°C without catalysts) for four different steels. Fig. 3 gives the change of the micro-hardness along the cross section of the nitrided layer as a function of the nitriding process for 35XMA steel for equal nitriding processes. Table 1 contains literary data on changes of certain parameters during the reactions. Table 2 gives the Cr content with depth of the nitrided layer for the 35XH3M steel. Table 3 gives hardness of the nitrided layer in the 15N scale as a function of the temperature and the holding time during nitriding.

TITLE: The Resistance of Metastable Nitrous Phases to Wear and Corrosion
(Stoykost' metastabil'nykh azotistyykh faz protiv iznosa i korrozii)

PERIODICAL: Tr. Leningr. in-ta aviats. priborostr., 1957, Nr 22, pp 23-28

ABSTRACT: Samples of technically pure Fe are nitrided and then quenched in various ways to produce nitrous surface phases, and are then tested for wear (W) on the Gordiyenko machine and for corrosion in 3% NaCl solution. The tests showed that a mixture of nitrous austenite and nitrous martensite has little W resistance, but that a martensitic phase has greater resistance, and that an ϵ phase is less resistant than martensite. All purely nitrous phases are less resistant than carbon martensite. Nitriding at 775°C of a specimen that had been subjected to cementation does not increase resistance to W. The high-nitrogen ϵ phase and nitrous martensite are more corrosion-resistant in 3% NaCl than are ferrite and carbon martensite.

TITLE: Tables of Thermodynamic Functions of Reactions Occurring During Chemical and Heat Treatment of Steel (Tablitsy termodinamicheskikh funktsiy dlya reaktsiy, vstrechayushchikhsya pri khimiko-termicheskoy obrabotke stali)

PERIODICAL: Tr. Leningr. in-ta aviats. priborostr. 1957, Nr 22; pp 33-77

ABSTRACT: The author outlines the procedures for computation of variations of isobaric-isothermal potential as a function of the temperature (ΔZ_T^0) of constant-pressure reactions; the computational procedures cover conditions when all necessary data (variations of heat capacity depending on the temperature, changes in heat content, and the standard isobaric-isothermal potential, ΔZ_{298}^0) may be obtained from handbooks, as well as instances when some of the information is not available. Values of coefficients (ΔH_0 , $-2.3\Delta a$, $-\frac{1}{2}\Delta b \cdot 10^3$, $-\frac{1}{6}\Delta c \cdot 10^6$, and I) from the formula

$$\Delta Z_T^0 = \Delta H_0 - 2.3 \Delta a T \log_{10} T - \frac{1}{2} \Delta b T^2 - \frac{1}{6} \Delta c T^3 + IT$$

Tables of Thermodynamic Functions (cont.)

are computed and tabulated for 266 separate reactions occurring during chemical and heat treatment of steel; auxiliary tables of thermodynamic functions of elements and simple substances permit calculating the values of these coefficients and determine the magnitude of the ΔZ_T^0 .

TITLE: Alitizing of Iron by Vapours of Aluminum Monochloride
(Alitirovaniye zheleza parami monokhlorida alyuminiya)

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, Nr 5,
pp 48-51 (USSR)

ABSTRACT: The authors calculated the changes of the standard isobaric-isothermal potential ΔZ_T^0 of the reactions taking place during alitizing of iron using data relating to the changes of ΔZ_T^0 between 600 and 1200°C which were published by Fichte, R. (Ref.3). On the basis of thermodynamic analysis it is concluded that for alitizing it is advisable to obtain AlCl compounds at temperatures above 970°C and for separating aluminium in accordance with the reaction expressed by Eq.(5), p.49, the temperature should be kept below 970°C, whilst the reaction of the alitizing proper can proceed at 1150°C. The authors also give the experimentally observed results on the interaction between iron and vapours of aluminium monochloride; "technical" iron of 8 mm dia, 30 mm long was subjected to the effect of AlCl vapours at 700-800 and at 950-970°C for a duration of one hour.

Alitizing of Iron by Vapours of Aluminum Monochloride 129-58-5-13/17

It was found that a hard, scale-resistant surface layer forms if the alitizing process is effected in the temperature range 950 to 1000°C; the strength of this coating is attributed to the formation of the inter-metallic compound Fe_2Al . If the alitizing temperature is higher, a less hard layer forms which appears to be a eutectic mixture of the phases FeAl_5 and FeAl_3 .

TITLE: Surface Strengthening of Titanium by Methods of Chemical-
Thermal Treatment

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
1960, Nr 3, pp 22-29 (USSR)

ABSTRACT: This is a description of an investigation prompted by
the unsatisfactory wear resistance of titanium and the
necessity of its surface strengthening. The present
work considers the possibilities and the results of
surface strengthening of titanium and contemplates the
future work in this direction. The phase composition
of the strengthened surface; oxidation of titanium;
nitriding of titanium; case hardening and cyaniding of
titanium; and boron treatment of titanium were studied
and described. The work of G. A. Meyerson and M. P.
Smirnov was mentioned. The authors arrived at the
following conclusions: (1) The industrial

Title : The Appearance of the Siberian Cedar in Several
Types of Pine Forests of the Priбайка́lie

Orig Pub: Tr. Vost.-Sib. fil. Akad. Nauk SSSR, 1957,
No. 5, 54-60

Abstract: The appearance of a growth of cedar under a
pine canopy has been noted in mossy and varied-
grass pine forests in the zone of contact be-
tween stands of pine and of cedar, sometimes at
a distance of 10-15 km. from the body of cedars;
this can be explained only by transport of the
cedar seeds by the Nutcracker *Nucifraga Cary-*
oactes/. Forming 0.6-0.7 of the young plants,

the cedars grow faster and higher than the pines,
thanks to their greater shade resistance and to
conditions less favorable to the growth of pines.
It is supposed that on mountain pine-green moss
areas the cedar will slowly squeeze out the pine
whose reforestation is difficult on a moss cover.
